## Monactinus simplex

## (Meyen) Corda, 1839

Most likely ID: n.a.

**Synonym:** *Pediastrum simplex, Micrasterias simplex* 

Sampling location: Pond of the waste disposal company Constance

Phylogenetic tree: <u>Monactinus simplex</u>

## **Diagnosis**:

- coenobium star-shaped, flat and single-Iayered
- diameter coenobium up to 250 µm
- coenobium of 4, 8, 16, 32, 64, (128) cells
- cell wall smooth or granulated
- marginal cells with a single, gradually tapering projection
- inner cells Y-shaped with intercelluar spaces, sometimes with a single central space
- marginal cells occasionally bearing tufts of mucilaginous spines
- one chloroplast, filling the cell
- single pyrenoid

I found *Monactinus simplex* in the plankton of the <u>pond of the waste disposal plant of</u>

<u>Constance</u> in September 2023 in large large quantities.

The genus *Monactinus* is easily recognized because the marginal cells have only one hornshaped process. Between the inner cells of *Monactinus simplex* large intercellular spaces are present (s. fig. 1 a). Sometimes the inner cells lacking so that the outer cells form a ring. The cell wall of the specimens in my population was granulated but noch covered with short spines as in the similar form <u>Monactinus simplex var. echinulatum</u>.

**Fig. 1 a-b:** *Monactinus simplex.*  $D = 85 \mu m$ . Two focal planes of a coenobium of 16 cells. There are intercellular spaces between the Y-shaped inner cells (a). The surface of this specimen is finely granulated (b). PY = pyrenoid. Obj. 100 X.
